Augmented Reality (AR) Technology has been widely utilized in many areas within the fields of education, research, and commerce. In recent years, the technology has been applied to the design, manufacturing, and maintenance of aircraft, as well as aviation personnel training. More specifically, AR maintenance instructions have been introduced to aviation maintenance training. These instructions include more interactive content, friendlier and more efficient user interfaces, enhanced visualizations and real-time data when compared to traditional paper or computer-based instructions. Hence, AR instructions have shown the potential to improve the quality and delivery of maintenance training in aviation (Macchiarella & Vincenzi, 2004).

Although research has been carried out to demonstrate the features and functions that AR-based maintenance instructions can provide, little research has been done to identify users' relative perception of the merits and drawbacks of AR maintenance instructions. Regardless of the actual benefits provided by AR maintenance instructions, their successful implementation within the maintenance training environment is rooted in the acceptance level of its potential users. Therefore, this study specifically targeted the perceptions of aviation maintenance students toward the use of AR maintenance instructions in aviation maintenance training operations. More importantly, the study used the Technology Acceptance Model (TAM) to explain and predict relationships among ease of use, usefulness, attitude, and intention regarding the implementation and use of AR maintenance training instructions.

Literature Review

Introduction to AR

AR is defined as the technology that overlays computer-generated data on top of a real image or view through a digital piece of hardware. AR consists of the display of information (text, images, videos, and interactive content) that augments a scene that is actively captured by a camera (De Crescenzo et al. 2011). The type of data displayed can vary from simple text lines to videos and even interactive 3D models. The hardware required to access and visualize the AR content consists of a camera, a display, and a data processing unit equipped with the proper software to achieve the task. This equipment is currently integrated – albeit at different quality and performance levels – in personal computers, cell phones, tablets and certain head-mounted devices (HMD) among others. AR has been used – or at least experimented with – in many domains, such as marketing, entertainment, as well as in medical and technical fields (Hincapie, Caponio, Rios, & Medivil, 2011).

AR has been the subject of much research and development over the past decade. This has led to the technology being tested and used in many sectors. As Ong and Nee illustrate (Nee, Ong, Chryssolouris, & Mourtzis, 2012; Ong & Nee, 2008), AR is being widely used in marketing and advertisement and has been successfully demonstrated and used in medical, military, entertainment, maintenance and manufacturing fields.

Current Aviation Maintenance and Training

Over the past few decades, the volume of air travel has considerably increased, and aircraft have become increasingly modern, complex and inclusive of numerous and diverse auxiliary systems. Thus, the concepts and processes associated with manufacturing, maintenance, and training – of aviation professionals – have also significantly increased in breadth and complexity. In turn, this has led to a large volume of reference material being necessary to perform tasks in the aforementioned fields. As highlighted in previous publications (Nee et al., 2012), manufacturing, for instance, has become much more complex and demanding and in virtually all cases requires the exchange of information in real time between different units of production.

Traditional methods of information delivery and exchange – specifically standard printed or digital texts and manuals – are still very widely used in the industry. Although they are cost-effective and well implanted throughout, they have several disadvantages when considered in the modern aviation world. Indeed, if one considers, for instance, the recurring need to update information (through Advisory Circulars, Airworthiness Directives or manufacturer publications), it is clear that traditional methods -consisting of end-user additions to publications for instance – incur undeniable inefficiencies and thus potential safety risks.

Also, workers in the field using traditional methods of information delivery typically experience many issues when performing given tasks. Indeed, instructions are usually detached from the equipment that the technicians are performing work upon - from a few inches away to potentially out of physical range -, which leads to the need to constantly switch focus between their instructions and work platform (Ong & Nee, 2008). This causes a high loss of time and productivity, as well as a higher potential for errors and injuries or damage.

In addition, as Hincapie et al. (2011) described, the information in traditional methods can be challenging to locate and extract. Indeed, workers and students – especially if inexperienced - can be led to frustration, poor performance,

and potentially costly mistakes when trying to find information in traditional texts and manuals.

Overall, in the aviation industry, data related to performing training or field technical operations is delivered primarily in one of two ways: through paper-based instructions and manuals or in digital format (Wang & Steven, 2014). The digital data is either similar in content and format to the paper-based instructions or may contain enhanced visuals and some level of interactivity. Each of these methods of data delivery has advantages, but also severe drawbacks, which lead to technical documentation being considered the primary human factors challenge in aviation maintenance. In fact, 45 to 60% of safety incidents were procedure related or involved technical documentation. Thus, there is a clear need for the implementation of new ways to deliver information to technicians for training and in the field that will facilitate retention of knowledge and execution of the tasks while decreasing errors and thereby diminishing safety hazards for the worker and ultimately the users of the aircraft (FAA, 2012).

Potential of AR Aviation Maintenance and Training

There have been many research projects involving AR in aviation maintenance operations and training. Many of these have focused on comparing augmented-reality methods of information delivery to currently common ones such as text, images, and video.

In aviation training and education, AR has been proven as a more effective learning tool than text or video-based methods (Macchiarella & Vincenzi, 2004), and could for instance help reduce training time and costs in maintenance, which typically amount to about 2000 hours (Hincapie et al., 2011). One project conducted by Ong, Yuan, and Nee, has demonstrated that AR is more effective than other forms of instructions, as it reduces errors and makes tasks easier (Ong, Yuan, & Nee, 2008). Another study by Macchiarella and Vincenzi (2004), which was designed to compare AR to video and text-based learning methods, compared short-term and long-term recollection of a topic in an aviation setting. The results obtained showed that AR produced significantly better long-term retention of information and thus was a better learning platform.

Beyond some of the efficiency improvements discussed above, AR can provide multiple new ways to enhance information delivery in aviation. In fact, as Kesim and Ozarslan (2012) noted, it allows for much better visualization and manipulation of objects and figures displayed on-screen. In addition, information is displayed in the user's field of view, which gives them the ability to assimilate it

better and concentrate more on the tasks to perform (Ong & Nee, 2008). The flexibility of AR also makes it applicable to several different types of processes and the AR-enhanced information is virtually always physically smaller (in weight and volume) than comparable information in print or other computer-based formats (Hincapie et al., 2011; Ong & Nee, 2008). This translates into more mobility, but also less time wasted accessing and retrieving information since the right information can be shown when and where it is needed (Ong & Nee, 2008).

In practical tasks then, AR provides the benefits of added efficiency, safety and reduced waste of resources. More recent research of graphics based air vehicle maintenance work instructions with user controlled augmenting data presentations (animated 3D models, interactive troubleshooting locations) during task-dense processes has shown that properly applied visualization and component presentation of technical or systems, when provided directly at the task location itself can improve efficiency and accuracy while resulting in reduction of rework due to missed or out of sequence steps (Hartman & Ropp, 2013; Kim et al., 2010). Although the literature has shown great features that AR-enhanced information can provide, research has yet to identify the users' perceptions of this new style of maintenance instructions. Given the fact that aviation maintenance students will undoubtedly be the future primary users of such AR-based instructions, this study focused on their reaction to the technology. To evaluate this, the Technology Acceptance Model was used.

Technology Acceptance Model

The Technology Acceptance Model (TAM) was developed by Davis (1986) by the Theory of Reasoned Action (TRA). TRA posits that one's behavior is directly influenced by behavioral intention that is a function of his/her attitudes and subjective norms toward the behavior (Davis, 1989; Masrom, 2007). Figure 1 depicts the Theory of Reasoned Action.

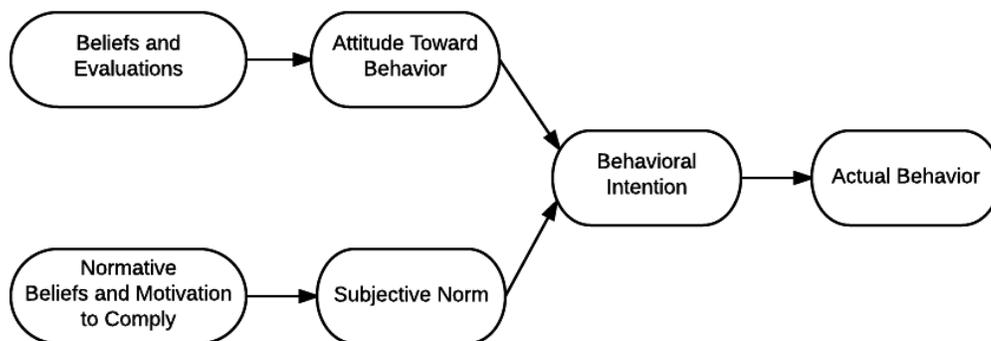

Figure 1. Theory of Reasoned Action

TAM aims to understand and explain user acceptance of a new technology (Davis, 1989). The model has been widely utilized by different research fields to understand and predict user behaviors. It provides a theoretical model to assist in explaining the relationships among external variables, perceived usefulness, perceived ease of use, attitude, intention to use, and actual use (Davis, 1989; Legris, Ingham, & Collette, 2004; Park, 2009). TAM proposes that external variables, perceived usefulness, perceived ease of use, attitudes, and intentions to use directly and indirectly affect a user's actual use of a technology system. Additionally, one's actual use and intentions are influenced by external variables via the mediators and predictors: perceived usefulness and ease of use (Davis, 1989; Masrom, 2007). Perceived usefulness refers to "the degree to which an individual believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320). By contrast, perceived ease of use refers to "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). Figure 2 presents the original TAM (Davis, 1989).

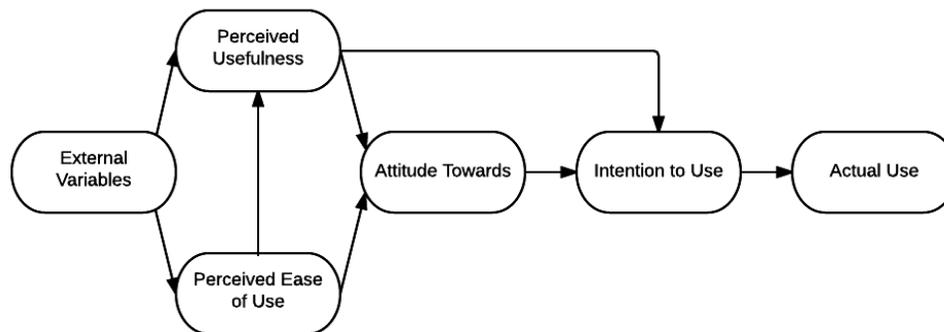

Figure 2. Original Technology Acceptance Model (Davis, 1989)

Masrom (2007) proposes a simplified TAM that excludes actual use and external variables. The researchers of this study utilized the simplified model to explain and predict the acceptance of aviation students using AR maintenance instructions. The following hypotheses were proposed by the researchers of this research study based on the simplified TAM (shown in Figure 3):

- H1: Perceived ease of use has a significant effect on perceived usefulness
- H2: Perceived ease of use has a significant effect on attitude towards using
- H3: Perceived usefulness has a significant effect on attitude towards using
- H4: Perceived usefulness has a significant effect on intention to use
- H5: Attitude towards using has a significant effect on intention to use

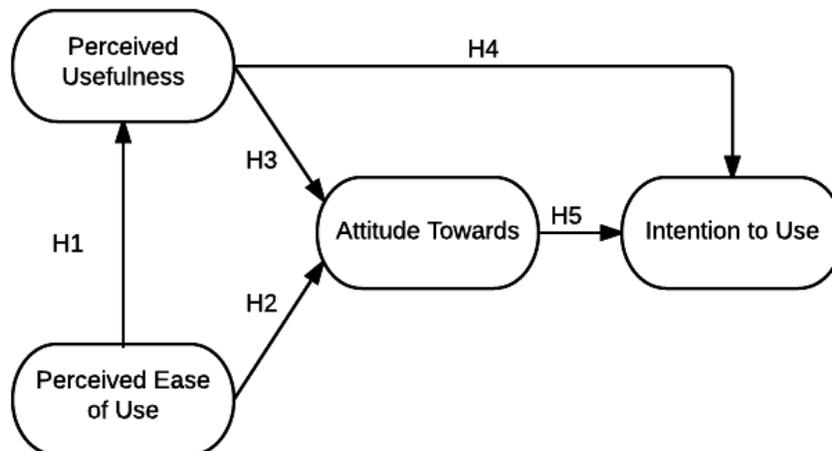

Figure 3. Hypotheses based on the simplified Technology Acceptance Model

Methodology

Participants

Forty-one participants who were undergraduate aviation students at a Midwestern university took part in this research study. All participants had at least two years of theoretical and practical experience conducting maintenance of aircraft systems in an educational setting. The practical task that the study was based on (F109 engine fan disassembly) was one that all subjects had previously had exposure to through paper-based maintenance instructions in a maintenance lab. Participants were contacted by the researchers in person and volunteered to participate in this study. Table 1 depicts the demographic information of the participants in this study.

Data collection

The data collection of this study consisted of two phases. During Phase one, the researchers demonstrated a set of AR maintenance instructions to participants. The AR demonstration was used to show the fan removal process of the F109 engine and to explain the features and usage of the AR software. The purpose of the demonstration was to allow participants to fully understand how to operate the AR instruction.

Table 1
Demographic information of participants

Items	Number (N)	Percent (%)
Gender		
Male	37	90.24
Female	4	9.76
School Year		
Junior	12	29.27
Senior	21	51.22
Did not report	8	19.51
Age		
18-21	18	43.90
22-24	21	51.22
25 or older	2	4.88
Total	41	100.0

During the second phase, participants were given a chance to use and interact with the AR instructions individually. They were then requested to complete a paper survey. The survey questionnaire of this study was adapted from Masrom's study (2007) and was intended to examine TAM for the implementation and use of AR instructions in aviation training operations. The survey included four demographic questions, sixteen 7-point Likert-type questions, and one open-ended question. The format of the 7-point Likert-type item used by the researchers was: 1-Strongly disagree, 2-Disagree, 3-Somewhat disagree, 4-Neutral, 5-Somewhat agree, 6-Agree, and 7-Strongly agree. The open-ended question aimed to obtain participants' comments on the future implementation of AR instructions in an aviation training setting.

Data analysis

The researchers analyzed the data obtained from the survey by using the SPSS statistical package. Factor analysis was used to test the construct validity of the survey questionnaire. Cronbach's Alpha reliability analysis was used to examine the internal consistency of survey items. Additionally, linear regression analysis was used to identify relationships among the variables: ease of use, usefulness, attitude, and intention to use AR instructions. The means of variables were used for regression analyses.

Results

Reliability analysis

To evaluate internal consistency and reliability of variables in this study, a Cronbach's alpha reliability analysis was conducted. A Cronbach's alpha value of greater than 0.7 is considered an acceptable reliability level (Tavakol & Dennick, 2011; Santos, 1999). All Cronbach's alpha values in this study were above 0.7, which demonstrated a high internal consistency and reliability. Table 2 shows the Cronbach's Alpha values for the internal reliability testing.

Table 2
Cronbach's Alpha Values

Item	Cronbach's α
Perceived ease of use	.738
Attitude towards using	.857
Perceived usefulness	.907
Intention to use	.885

Factor analysis

Factor analysis was utilized to examine the construct validity of four factors: perceived ease of use, attitude towards using the technology, perceived usefulness, and intention to use. Four items were included in the survey questionnaire to measure each factor. A factor analysis score greater than 0.6 is considered a good level of survey validity (Chesney, 2006). All of the factor analysis scores in this survey were greater than 0.6, which showed a good validity and reliability of the survey. Table 3 displays the results of the factor analysis.

Regression results

A separate linear regression analysis was conducted to test Hypothesis 1 (H1), in which perceived ease of use was used as an independent variable, and perceived usefulness was used as dependent variable. As shown in Table 4, Hypothesis 1 (H1) failed to be rejected with $\beta = .677$ and $p < .001$. Therefore, perceived ease of use has a significant effect on perceived usefulness.

Hypothesis 2 (H2) and Hypothesis 3 (H3) were tested by using linear regression analyses (the regression results indicated in Table 5). The regression results indicated that both perceived ease of use and perceived usefulness have a

significant effect on attitude towards using with $p < .001$. Therefore, both Hypotheses 2 and 3 (H2 and H3) failed to be rejected.

Table 3
Factor analysis results

Item	1	2	3	4
EOU 1	0.69			
EOU 2	0.88			
EOU 3	0.60			
EOU 4	0.79			
PU 1		0.87		
PU 2		0.90		
PU 3		0.92		
PU 4		0.85		
ATT 1			0.86	
ATT 2			0.87	
ATT 3			0.81	
ATT 4			0.85	
INT 1				0.86
INT 2				0.84
INT 3				0.88
INT 4				0.88

Note. EOU= Perceived ease of use; PU = Perceived usefulness; ATT = Attitude toward using; INT = Intention to use

Table 4
Linear regression result for hypothesis 1

	β	p	t	R^2
Perceived ease of use	.677	<.001	5.581	.458

Table 5
Linear regression results for Hypotheses 2 and Hypothesis 3

	β	p	t	R^2
Perceived ease of use	.594	<.001	4.667	.353
Perceived Usefulness	.850	<.001	10.210	.723

Similarly, Hypothesis 4 (H4) and Hypothesis 5 (H5) were tested by linear regression analyses with perceived usefulness and attitude as independent variables, and intention to use as a dependent variable. The regression results indicated both perceived usefulness and attitude towards using have a significant effect on intention to use. Therefore, both Hypothesis 4 (H4) and Hypothesis 5 (H5) failed to be rejected.

Table 6

Linear regression results for Hypothesis 4 and Hypothesis 5

	β	p	t	R^2
Perceived Usefulness	.643	<.001	5.310	.413
Attitude Towards using	.601	<.001	4.762	.362

Discussion

Across all participants of this research study, there were not any indications of negative attitudes regarding the development, use, and implementation of AR maintenance training materials. Survey respondents expressed overall support for incorporating AR-based maintenance instructions into maintenance training operations. As one survey respondent stated: “The use of Augmented Reality would vastly improve the quality of learning in all AET classes.”

The applicability of TAM to aviation student acceptance of AR technology was fully supported. According to survey responses, participants acknowledged and appreciated the advantages that AR instructions provide regarding ease of use and usefulness. Both ease of use and usefulness had a significant effect on aviation students’ attitude toward using AR instructions. Also, students’ intention to use AR technology was indirectly and directly affected by ease of use and usefulness respectively. Therefore, improving ease of use and usefulness may play a very important role in determining a successful implementation of AR training material. This confirms that two of AR designers and developers’ key emphases should be on usefulness and ease of use. Furthermore, the survey results showed that aviation students’ attitude had an impact on their intention to use an AR technology. A positive attitude from aviation students should be established to ensure a success of the future AR implementation.

There are some limitations of this research study that must be acknowledged. Due to a limited number of aviation maintenance students at the Midwestern university surveyed, this study had a small sample size, which could restrict this study from coming to a persuasive conclusion, especially from a quantitative

analysis standpoint. In addition, the research study did not examine the full (original) TAM. Two constructs, actual use, and external variables were not included in the TAM examination. What follows are recommendations for future studies to deal with the limitations.

In future studies, research including a larger group of participants is recommended. Also, future research studies should include other possible AR users, such as aviation maintenance lab instructors who may use AR maintenance training instructions to instruct aviation students to conduct maintenance operations, or maintenance professionals, who would have experience in the domain. Their perceptions and attitudes towards the use of AR instructions would be very helpful in enhancing the future design and development of AR based instructions. Additionally, some experimental studies to compare AR and traditional (paper or digital) maintenance instructions in efficiency and accuracy can be carried out. For example, two groups of aviation students use AR and paper instructions respectively to perform the same maintenance task. Some measurement metrics could be accuracy, overall time, and other comparative respects.

Conclusion

The purpose of this study was to examine TAM for aviation students' acceptance of AR instructions and to identify perceptions and attitudes of aviation maintenance students about the future utilization of AR maintenance manuals in aviation maintenance training. The findings confirmed that TAM could be a useful theoretical model to help gain a clearer understanding of relationships among usefulness, ease of use, attitude towards using, and intention about the implementation of AR instruments. From an overall view, survey respondents accepted and supported the future use of AR maintenance materials. More importantly, this study was one of the first studies to incorporate TAM in AR implementation of an aviation training setting. The results may lay a foundation for future researchers and AR developers dealing with the AR implementation in the aviation industry.
