Abstract
It is imperative when utilizing educational video games in K-12 classrooms that student preferences with regard to
game play, purpose, and design be considered in order to maximize game play efficiency for learning. As Web 2.0
content infiltrates our educational medium, student customization is key. This manuscript intends to share
customization requests gleaned during an 18-week experimental study examining educational video game effects
upon 7th graders enrolled in Mathematics and Mathematics 2 courses.

Introduction
There are controversial findings found within the literature during the past decade, discussion
provided within the Historical Perspective section of this article, concerning the many
possibilities for learning, or lack thereof, with regard to utilizing educational video games as
learning tools. One such area of discomfort for the field stems from a possible inequality
between the sexes when utilizing educational video games as a teaching medium. However, as
diffusion of technology occurs with successive generations, concrete, yet repetitive, empirical
evidence is needed to expose true and consistent empirical support in order for future research to
become more powerful while allowing our field of Educational Research and Instructional
Design to move beyond stereotypes, unfounded beliefs, and educational video game bias. This
manuscript intends to share findings from an eighteen-week experimental study, conducted
during the 2008-2009 school year, examining educational video game affects in a K-12
classroom between the sexes; one that posits social collaboration and tool utilization are one with
end user customization as the driving force. Such interface demands inform designers to the
varying customization requests of the digitally fortunate, while squashing previously perceived
educational differences reported between the sexes with regard to game play and repurpose of
educational tool.

Study
An experimental research study was conducted to examine educational video game effects on
mathematics achievement and motivation between sexes to aid to the empirical evidence. A pre
and post interview sample was randomly generated to explore the views of the treatment group,
derived from 7th grade mathematics (Mathematics 2/Mathematics 2 Advanced) class (n=60)
learning algebra.
The study took place over an 18-week middle school session or term and applied an educational video game as the treatment. The applied treatment included a suite of single and multi-player educational mathematics video games that addressed pre-algebra and algebra concepts designed in mission format. The game consisted of 20 missions or levels; all aligned to both state and national mathematics standards. The video game suite provided visual and verbal feedback designed to engage students in the learning of algebra concepts. The treatment has been advertised by the vendor as providing an immersive 3-D video game and gaming world for learning.

Although this article provides a summary of quantitative findings, the majority of this article is dedicated to the presentation of the qualitative data as the researcher believes these date usurp quantitative findings uncovered through statistical calculation since game play is considered an individual experience (Gee, 2003). Pre/post interview data surrounding the likes, dislikes, suggested game improvements, and overall acceptance of game play in comparison to traditional teaching methods compose the qualitative aspect of this study.

Sample
The population for this study was comprised of a large urban Florida county middle school, specifically 7th graders. A purposeful sampling strategy obtained included one consenting middle school teacher, along with 60 7th graders (males=29, females=31), not taking Algebra I or PreAlgebra offerings. The subject of algebra is somewhat unusual to address in normal 7th grade Mathematics 2 (n=43) or Mathematics 2 Advanced (n=17) mathematics classrooms. For course benchmark description, please refer to the Florida Department of Education references.

Historical Perspective
With time and improvement in technology (Reese, 2007), mathematics and sex difference research has begun to focus on a new mathematics teaching trend, one that invokes game play in mathematics classrooms. According to Lim, Nonis, & Hedberg (2006), technology is simply an extension of a student’s daily activity not a tool needing explanation, therefore, are worth considerable exploration to improve education.

Not all findings, however, have supported the use of educational video games in the classroom (Kafai, 2006). Negative perceptions with regard to video games have surfaced (Mubireek, 2003). Rice (2007) summarized the views of some stakeholders that video games are “mindless forms of activity and do not hold an affinity to strong instructional content.” Rice noted that some stakeholders have associated violence to video games but also acknowledged that those who had little to no game play exposure have made many of the negative comments documented with regard to video game usage in the classroom.

Prensky (2001) has reported that teachers are, for the most part, “digital immigrants” and their philosophy of teaching and/or teaching methods needs to change to match their intended audience. Game play when learning mathematics has begun to be explored as a true potential for learning (Amory, 2007; Kafai, 2006; Ke & Grabowski, 2007; Sedighian & Sedighian, 1996). A presumption made is as diffusion of technology with successive generations disappears, video game play and technology bias from stakeholders may naturally disappear (Provenzo, 2000; Rice, 2007). Nonetheless, Rice identified several barriers that can add to the overall negative
perception. These included (a) game graphic quality, (b) lack of classroom time for game play, and (c) inadequate representations of learning objectives when deploying video games as a teaching mechanism. Rice also observed the “negative perceptions surrounding the term (gaming) itself,” when speaking of in-class game play.

In an attempt to explain video game play differences between the sexes, researchers specifically identify game content and design as a potential cause of the perceived lack of female video game play results (Agosto, 2004; Hayes, 2005; Jones, 2005; Ray, 2004; Valenza, 1997). Additionally, Hayes and Dickey (2006) have suggested that the market needs to address female-only video game creations in order to capture the attention of the female audience. However, Entertainment Software Association (ESA) (2007), as presented in their 2007 Sales and Demographic Report, suggested that females are “gaming” and countered Hayes’ (2005) and Dickey’s (2006) stated need for more female-only game creations.

In order to attract female gamers it has been suggested that current video game designs need to remove sex and racial bias (Agosto, 2004; Mou, 2007) or content related to “hyper-sexualized stereotypes,” (Ray, 2004, p. 35). Beginning as early as the 7th grade, females are subject to varying levels of maturity, and content including sex stereotypes or images could lead to embarrassment and create additional barriers to learning. The video game play experience then becomes a “turn-off” to the female sex (Valenza, 1997), thus, again, leading to an inequality in learning environment if being used as a learning tool.

A secondary grouping of video game play barriers dealing with video game designs include violence, negative sex stereotypes, or the lack of social aspects inclusion have contributed to the lack of female video game play (Agosto, 2004; Hayes, 2005; Jones, 2005; Ray, 2004; Valenza, 1997). If addressing only the social aspect of gaming, Gee (2003) stated each participant approaches an activity, or game play, in a very unique and individual manner; thus, one may deduce that video game play lacks social aspects. Whereas, Braun, Goupil, Giroux, & Chagnon (2001) stated that verbal and social preferences are important attributes for girls when playing games of all types. Furthermore, video games offering only individual game play experience without socialization components have not been found to provide an attractive option or learning activity for girls. According to Damis-Paraboschi, Lafont, & Menaut (2005), “girls prefer verbal exchanges” (p. 180). If a game’s design is missing social aspects, the game will likely not be preferred.

Although video game play findings have been positive overall, Braun et al. (2001) indicated that boys had a stronger affinity for video game play than girls. This suggested a possible inequality in learning environment between the sexes. To be a successful teaching tool in the classroom, future learning must include a “desirable learning environment such that children can enter the environment with little to no knowledge of the embedded mathematical concepts” (Sedig, 2008) and without a need to overcome a learning curve or tool, such as an educational video game.

Lastly, Reese (2007) reported the historic lack of exposure to video games and video game play by females can detract from a female’s ability to utilize prior knowledge during a learning event. Activation of prior knowledge and the ability to relate to previous experience is necessary when learning. Jones (2005) has stated that the lack of video game play or exposure ultimately fails
girls as they cannot “achieve goals, develop strategies, and cooperate in groups while competing” (p. 2), thus severely detracting from the learning experience.

In summary, male familiarity with both the tool and the video gaming environment (Daviault, 2000) will continue to be seen as a disadvantage for females unless females are provided with a properly aligned tool for learning. If game designers keep to the current game development strategies of not including female preferred content, or if applying this information to educational learning tool selection processes, educators and administrators, alongside designers, will errantly implement video games without an understanding of video game play and preference between the sexes. Therefore, males will continue to have a learning advantage in all areas of curriculum when video games are utilized.

Findings
A repeated-measure (SPSS v14) was used to examine results. The analysis included ethnographic results from both student and teacher interview and observation sessions for data triangulation. Results revealed a statistically significant academic mathematics achievement score increase (F = 21.8, df = 1, 54, p < .05). Although, mathematics class motivation scores did not present significance (F = .79, df = 1, 47, p > .05), both sexes posted similar data outcomes with regard to mathematics class motivation after using the treatment in conjunction with receiving in-class instruction. Additionally, there was an increase in male variability in standard deviation score (SDmotivationpre = 8.76, SDmotivation post = 11.70) for mathematics class motivation. Furthermore, data indicate there is no disadvantage for one sex over the other when learning within an educational video game setting.

Self-reported differences between the sexes for this limited sample regarding game design and observed female game play tendencies were also investigated. The data presented customization as a unified, and most requested, game design need between the sexes. Between sex differences were found only to be superficial other than a female delay in game acceptance regarding time and game play comfort.

During the interview process, it quickly became apparent that these students had previous exposure to video games during their schooling. This exposure caused a comparison to the treatment, thus, having a majority of students agree (n = 32; positive = 28) that video game play was preferred to that of traditional methods which may no longer hold student interest to the extent that games can. Technology appeared to skew student acceptance of traditional teaching methods.

Students did however appreciate the ability to create and stay active while learning, but found the simplest game additions or removal of tools to be annoying. In total, shooting, war games, and character creation were high on the list of student acceptance. In the end, time spent away from the technology such as game lag or hardware freezing, created a longer than expected game return waiting period expressed by seven of the eight student interview groupings; thus, computer architecture represented 50% of the main source of irritate when playing video games in a learning environment.
It was observed by both teacher and researcher that the longer females stayed at the computer screen and involved with the video game, the easier it appeared for females to ask questions and present an increased likelihood to move beyond the initial confusion of the tool. Conversely, males appeared to have initial tool confusion, but expressed great fun in collaborating with each other; whereas, females demonstrated a need to thoroughly review game directions to achieve a confidence level to that of their male counterparts.

Conclusion
Based upon this study’s findings, teachers who are looking to implement educational video games in K-12 classrooms need to follow structured implementation plans to ensure technology is properly integrated. Teachers need not be overly concerned about their personal levels of video game play ability, although helpful; they should have a general familiarity of the implemented educational tool. Familiarity of tool used in conjunction with structured implementation plans would additionally help to produce the desired educational outcome. Furthermore, educators should use vendor and school-specific implementation tools, when available, if electing to utilize an educational video game as a teaching tool or media (Kebritchi, M., Hirumi, A., Kappers, W., & Henry, R., 2008).

Educators are responsible for maintaining equal opportunities for all students (Entertainment Software Association (ESA) 2007). Therefore, teachers need to take on the task of demanding more from gaming and software companies. Game companies should survey both teachers and students alike while creating games to gather content design suggestions.

Based upon this study, differences between the sexes, when utilizing an educational video game for learning, appear only superficial, as females appear to present no outstanding achievement or motivation differences during examination. However, research regarding educational video games pertaining to instructional design outcomes must continue until overarching findings agree.

Agnostic educators must take note that games provide the impetus for academic learning. It is, however, not in the endogenous nature of students to view video game play as learning since students do not immediately associate fun or entertainment as learning. Thus, when examining motivation as a barrier to learning, the lack of significance in motivation for a topic does not necessarily equate to a negative achievement outcome. The onus of learning falls upon the teacher and district to balance the use of an emergent technology with in-class pedagogy experiences to benefit both sexes.
